

Are the structures more tree-like than chance? (all tests pooled)

Left of the dashed line: fewer laminar families than randomly placed spans give.

○ Arbitrary layers ● Span placement

Observed families ÷ null median (log scale; grey bar: span-placement null, 5th–95th percentile)

Span placement: 17 of 22 below the null median (5 above, 0 on it); sign test $p = 0.0084$; Fisher's combined $p = 2.7e-05$.
 Arbitrary layers: 19 of 22 below the null median (3 above, 0 on it); sign test $p = 0.00043$; Fisher's combined $p = 7.6e-07$.
 The structures share test batteries, authors and in some cases language families, so neither figure is a test on independent cases.
